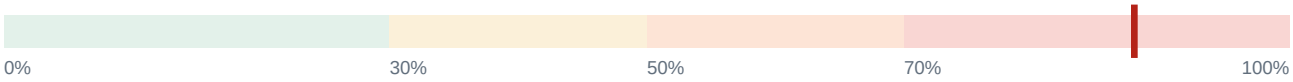
CardioSense · Cardiovascular risk report

Report #1 | Patient: OPD-2026-0412 | Generated 16 Oct 2026, 13:48 UTC by Dr Priya Rao

88% Very high risk

Estimated probability of cardiovascular disease from the Deep Neural Network model.

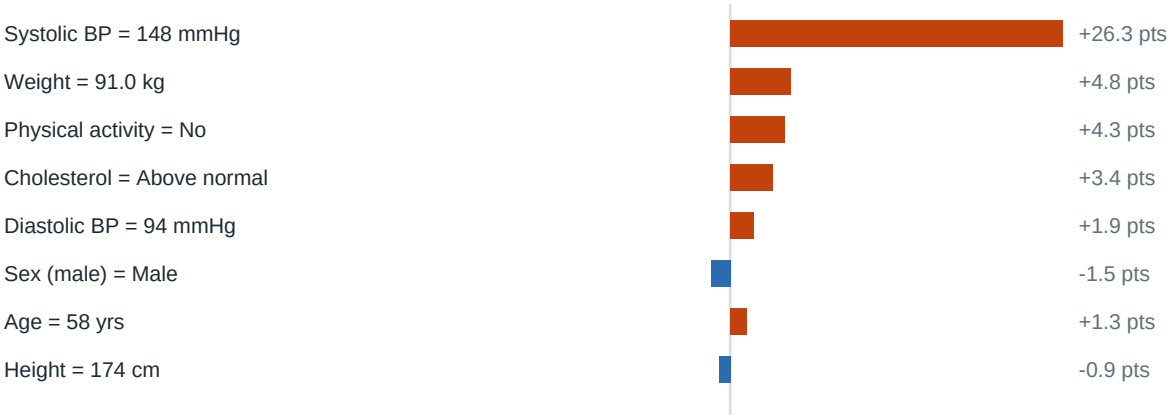


Patient measurements

Age	58 years	Systolic / diastolic BP	148 / 94 mmHg
Sex	Male	Pulse pressure	54 mmHg
Height / weight	174 cm / 91.0 kg	BMI	30.1 kg/m^2
Cholesterol	Above normal	Glucose	Normal
Smoking	Yes	Alcohol intake	No
Physically active	No		

What drives this estimate

Average risk across reference patients is 48%. Bars show how many percentage points each measurement adds (orange) or removes (blue) for this patient (Kernel SHAP).



Suggested follow-up

- Model estimates high cardiovascular risk; consider a full clinical cardiovascular assessment.
- Blood pressure is in the hypertensive range (>=140/90 mmHg); confirm with repeat readings and review management.
- Cholesterol is above normal; a full lipid profile and dietary review are recommended.
- BMI is 30.1 (obese range); structured weight management would lower cardiovascular risk.
- Smoking is a major modifiable risk factor; offer cessation support.
- Patient reports no regular physical activity; aim for at least 150 minutes of moderate activity per week.

This report is produced by a machine-learning model trained on 68,576 examination records (test accuracy about 73%, AUC 0.80). It is a decision-support aid for qualified clinicians, not a diagnosis, and must be interpreted together with clinical judgement.
